**Report
Cruise 234 RV WALTHER HERWIG III
30.11. - 21.12.2000**

Scientist in Charge: Dr. Thomas Lang

1 Abstract

As in December 2000, the prevalence of lymphocystis in North Sea dab (*Limanda limanda*) was below levels recorded previously. The highest prevalence of 21,7 % was recorded in area N06 off the Scottish coast (Firth of Forth). Strikingly low prevalences of acute/healing skin ulcerations with maximum values of 3,3 % (area N06) and 2,8 % (Dogger Bank, area N04) were found. In contrast, prevalences of hyperpigmentation (green to black discolouration of the skin) were increased, with maximum levels of 42,5 % (area N04) and 37,7 % (area N06). In dab from the Baltic Sea, all externally visible diseases monitored occurred at much lower prevalences.

In cod from the Baltic Sea, prevalences of acute/healing skin ulcerations continued to occur at high prevalences, particularly in a region north and east of the island of Rügen (areas B10, B11, B03). Prevalences recorded were as high as 12,0 %, 12,9 % and 16,6 %, respectively. In the same areas, elevated prevalences of skeletal deformities were again recorded (6,6 %, 4,6 % and 5,6 %, respectively).

2 Programme

1. Studies on the occurrence of fish diseases and parasites
2. Studies on biological effects of contaminants in the framework of the EU-funded project BEEP
3. Sampling of fish, zooplankton, sediment and surface water for chemical analysis of radioactive substances, heavy metals and organic contaminants
4. Hydrographical measurements (salinity, temperature, oxygen)
5. Sampling of livers and other organs of fish for subsequent histological and biochemical studies
6. Studies on the occurrence of *Ichthyophonus* sp. in herring (*Clupea harengus*)

3 Cruise dates

RV Walther Herwig III left Bremerhaven on 30. November 2001 at 11:00 h heading for the Baltic Sea. After passing the North Sea/Baltic Sea Channel she arrived in Kiel, where five guest scientist taking part in the sampling programme for the EU-funded project BEEP were taken on board. Practical work started in the morning of 2. December in area B10 southeast of Rügen. The further dates can be seen in Fig. 1 und Tab. 1. After finishing the practical work in the Baltic, the RV returned to Kiel in the evening of 11. December, and the guest scientists left in the morning of 12. December. After the passage of the North Sea/Baltic Sea Channel, the work was continued in the North Sea in area N01 in the German Bight on 13. December. Studies were continued in five additional North Sea areas (see Fig. 1 und Tab. 1). Because of a storm that made further activities impossible the cruise was terminated in the evening of 20. December 2001 in Bremerhaven.

3.1 Fishery

Numbers and weights of cod (*Gadus morhua*), haddock (*Melanogrammus aeglefinus*), whiting (*Merlangius merlangus*), plaice, (*Pleuronectes platessa*), common dab (*Limanda limanda*) und flounder (*Platichthys flesus*) caught per one hour of trawling are shown in Fig. 2 and Fig. 3 .

4 Preliminary results

4.1 Common dab (*Limanda limanda*)

3217 dab were inspected for the presence of externally visible diseases. The results are shown in Tab. 2. The prevalences of lymphocystis in the North Sea were in the range of 4,9 % (area N01) to 21,7 % (N06). In the Baltic Sea, the prevalences were lower with values of 1,4 % (area B01) and 2,0 % (area BEEP5). Prevalences of epidermal hyperplasia/papilloma in the North Sea were in the range of 1,0 % (area N05) und 6,0 % (area N04), whereas levels in the Baltic were 0,0 % (area BEEP5) and 0,4 % (area B01). Acute/healing stages of skin ulcerations were between 0,2 % (area N05) and 3,3 % (area N06) in the North Sea, and in the Baltic Sea, levels of 0,3 % (area BEEP5) and 0,2 % (area B01) occurred. Hyperplasia of the gills (X-cell-disease) were recorded in up to 3,3 % (area N22) and 4,2 % (area N06) of the North Sea dab. The most frequent externally visible anomaly of dab continued to be hyperpigmentation (green to black discolouration of the skin). Prevalences were in the range of 5,6 % (area P01) to 42,5 % (area N04). This condition was absent in Baltic Sea dab.

4.2 Cod (*Gadus morhua*)

In total, 2648 cod from the Baltic Sea were examined. Highest prevalences of acute/healing stages of skin ulcerations were recorded in areas B03 (16,8 %), B11 (12,9 %) and B10 (12,0 %). These values were considerably lower than in December 2000, but still elevated compared to long-term values recorded before 1998 (the year when prevalences drastically increased for the first time). The maximum recorded prevalences of grossly visible skeletal deformities were 6,6 % (area B10), 5,6 % (area B03) and 4,6 % (area B11). It was again noted that areas with maximum prevalences of skin ulcerations and skeletal deformities were identical. Pseudobranchial pseudotumours (X-cell-disease) were recorded in areas B05 (0,2 %) and B11 (0,6 %). The results of parasitological studies regarding prevalences of *Lernaeocera branchialis*, *Clavella adunca* und *Cryptocotyle lingua* are listed in Tab. 3. Because of the extremely low number of cod

caught in the North Sea (reflecting the generally poor condition of this stock) , no disease studies were performed.

4.3 Flounder (*Platichthys flesus*)

Prevalences of lymphocystis in Baltic Sea flounder (n = 682) were between 14,4 % (area B10) and 41,9 % (area B03), and those of acute/healing skin ulcerations between 0,0 % (area B09) und 16,7 % (area B05) (see Tab. 4).

4.4 Liver anomalies in dab and flounder

Baltic Sea

In Baltic Sea dab examined (n = 93), no liver nodules > 2 mm in diameter were noted. In Baltic flounder, only two specimens (18,2 %, n=11) from area B09 showed liver nodules (see Tab. 5 and Tab. 6). These finding confirm the results of studies carried out in previous years, indicating generally low prevalences of liver tumours in flatfish from the south-western Baltic Sea.

North Sea

582 dab were inspected for the occurrence of macroscopic liver anomalies. The results (see Tab. 5) confirm that prevalences of liver nodules/tumours continued to be low compared to the late 1980s and early 1990s. Highest levels in dab \geq 25 cm total length occurred in areas N04 (10,2 %), N01 (11,1 %) and N22 (13,6 %) auf. All macroscopic nodules were fixed for later histological and histochemical confirmation of the lesion. In addition to the macroscopic screening, tissues (liver, spleen) of 50 specimens per area were fixed for routine histopathology .

Regional hot spots of green liver discolouration (vcaused by parasitic infection with myxosporidians), liver nematodes and acanthocephaleans again were areas N05, N06 und N22. Prevalences and intensities were comparable to those observed in previous years.

5 Additional sampling

In the framework of the EU-funded project BEEP (‘Biological Effects of Environmental Pollution in Marine Coastal Ecosystems’), four additional areas (BEEP1, 2, 3, 5) were visited in order to study biological effects of contaminants on Baltic flounder. Samples were taken for a wide range of biomarker techniques. In parallel, hydrographic measurements and sediment sampling for assessing sediment toxicity were carried out.

In areas B01, N01, N04, N06 und P01, liver tissue from 20 female dab each, size group 20-24 cm total length, was snap-frozen for enzymatic measurements (EROD and GST activities).

7 Participants

1. Dr. Thomas Lang, IFÖ AST Cuxhaven (Fahrtleiter)
2. Ursula Kürschner, IFÖ AST CUX
3. Gunther Nagel, IFÖ
4. stud.biol. Kerstin Jerosch, Humboldt-Universität Berlin
5. stud.biol. Ika Neven, Humboldt-Universität Berlin
6. stud.biol. Paul Kotterba, Ernst Moritz-Universität Greifswald

7. Justyna Kopecka, Institute of Oceanology, Sopot (Polen)
8. Henrik Sundberg, Stockholm University, Stockholm (Schweden)
9. Jari Parkkonen, Göteborg University, Göteborg (Schweden)
10. Edvardas Bagdonas, University Vilnius (Lithuania)
11. Heide Lück, Tierärztliche Hochschule Hannover
12. Dr. Doris Schiedeck, Institut für Ostseeforschung, Warnemünde
